

**Part-A: Question-4**

To add video support, I would follow the same Strategy pattern used for sharing. I would create a VideoStrategy interface with a method like captureVideo(), plus two implementing classes: VideoCapture, which records video, and NoVideo, which does nothing. In CameraApp, I would add a VideoStrategy field, a setter such as setVideoStrategy() so the behaviour can change at runtime, and a method like performVideoCapture() that delegates to the strategy.

BasicCameraApp and AdvancedCameraApp would set their defaults in their constructors, for example NoVideo for Basic and VideoCapture for Advanced. The existing sharing classes and methods would not change, and new video behaviours could be added later without modifying CameraApp. Finally, the class diagram would be updated to show the new interface, its two implementations, and the association from CameraApp.
